Job Portal System — CareerSpring

Internship Project Report

Introduction

The Job Portal System is a web application that connects job applicants and employers. Applicants can search opportunities, submit applications, and track progress. Employers can publish job listings and review candidates.

Abstract

CareerSpring is built using Java and Spring Boot, with Thymeleaf for server-rendered pages. Spring Security provides login, registration support, password hashing, and role-based access. Spring Data JPA manages Users, Jobs, and Applications. Features include keyword search, job-type filtering, job posting, duplicate-application prevention, and application status updates. The interface uses responsive colourful styling. An embedded H2 profile supports quick local demos, while a MySQL profile is included.

Tools Used

Java 17; Spring Boot; Maven; Thymeleaf; HTML and CSS; Spring Security with BCrypt; Spring Data JPA/Hibernate; H2 for quick local execution; MySQL profile; Visual Studio Code or another Java IDE.

Steps Involved in Building the Project

1. Created a Spring Boot Maven project and added web, Thymeleaf, JPA, Security, validation, H2, and MySQL dependencies.
2. Designed the users, jobs, and applications entities and corresponding JPA repositories.
3. Configured registration, login, password hashing, and role-based access for employer and applicant accounts.
4. Built pages for home, registration/login, job search/details, employer dashboard, and applicant dashboard.
5. Implemented job posting, applications, application status changes, search, and job-type filters.
6. Added demo accounts and sample jobs, responsive styling, quick-start H2 settings, and a MySQL profile.

Conclusion

The project demonstrates the core workflow of a job portal for two roles. It combines authentication, job discovery, posting, applying, and status tracking in one application. Future enhancements could include resume uploads, email notifications, pagination, and production deployment.
